

AeroSphere

DRONE · 360° · EDITOR — USER MANUAL

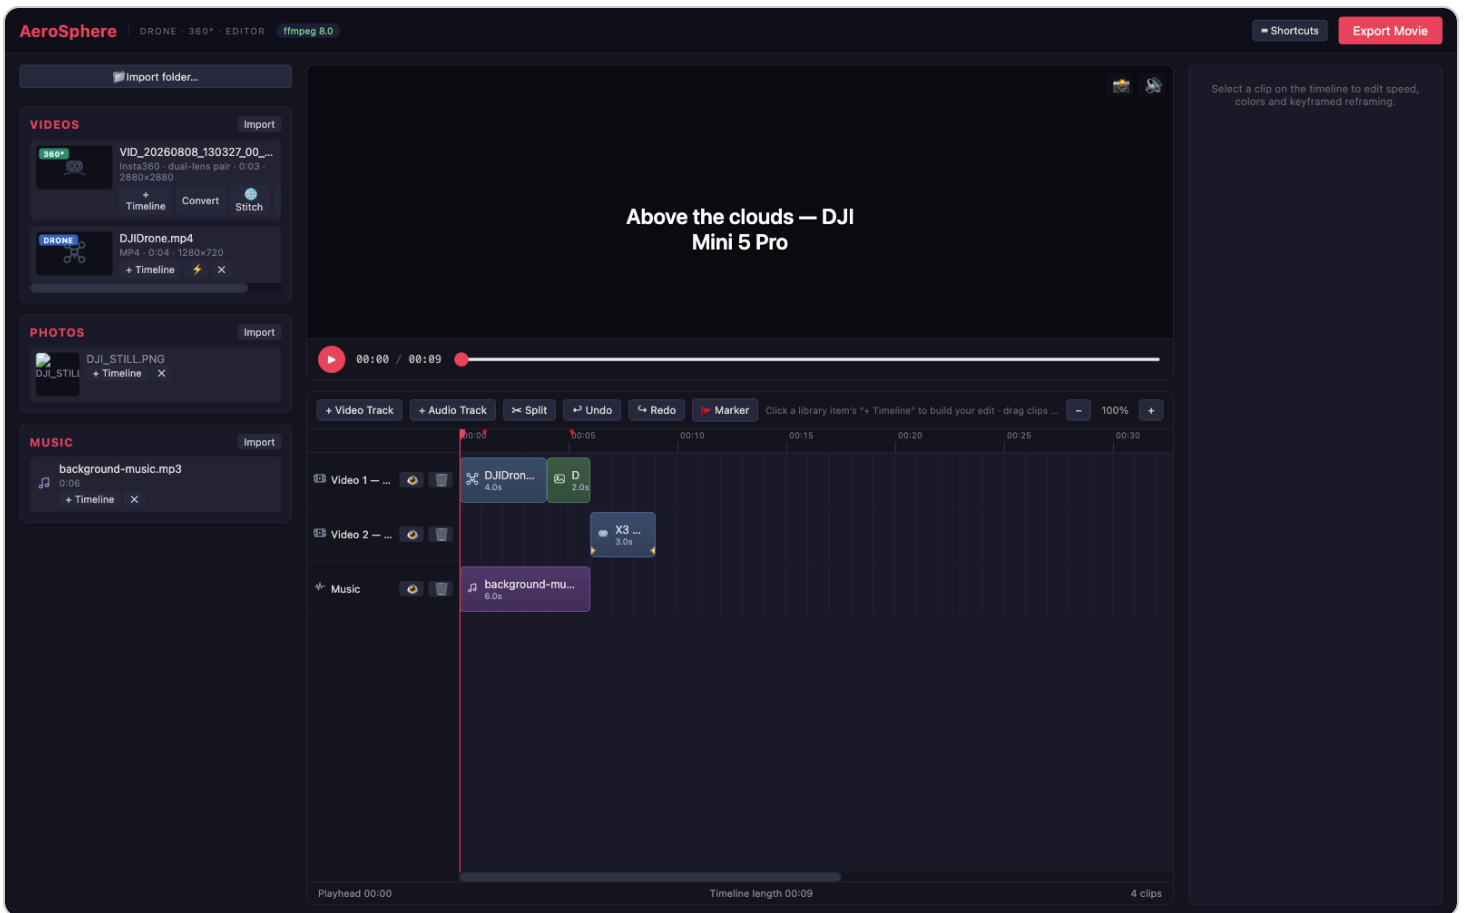

AeroSphere is a desktop video editor built for **DJI drone** footage and **Insta360 X3** 360° cameras. Reframe 360° shots with keyframes, grade D-Log clips, burn flight-telemetry overlays, edit with multi-track audio, speed ramps, titles, dissolves and export masters for YouTube, Instagram, Facebook or cinematic delivery.

Created by **Anurag Mallick** · github.com/anurag-mallick

1 · Launching the app

AeroSphere ships as a native macOS application.

How: Double-click **AeroSphere.command** in the project folder. The first launch installs dependencies and builds **AeroSphere.app**; afterwards the app opens directly like any normal program (drag it into /Applications if you like). Terminal alternative: `./start.sh` (developer mode). Requirements: Node.js ≥ 18 and FFmpeg (`brew install ffmpeg`).

The main window: media library (left), preview + transport (top right), timeline & inspector (bottom).

2 · Importing media

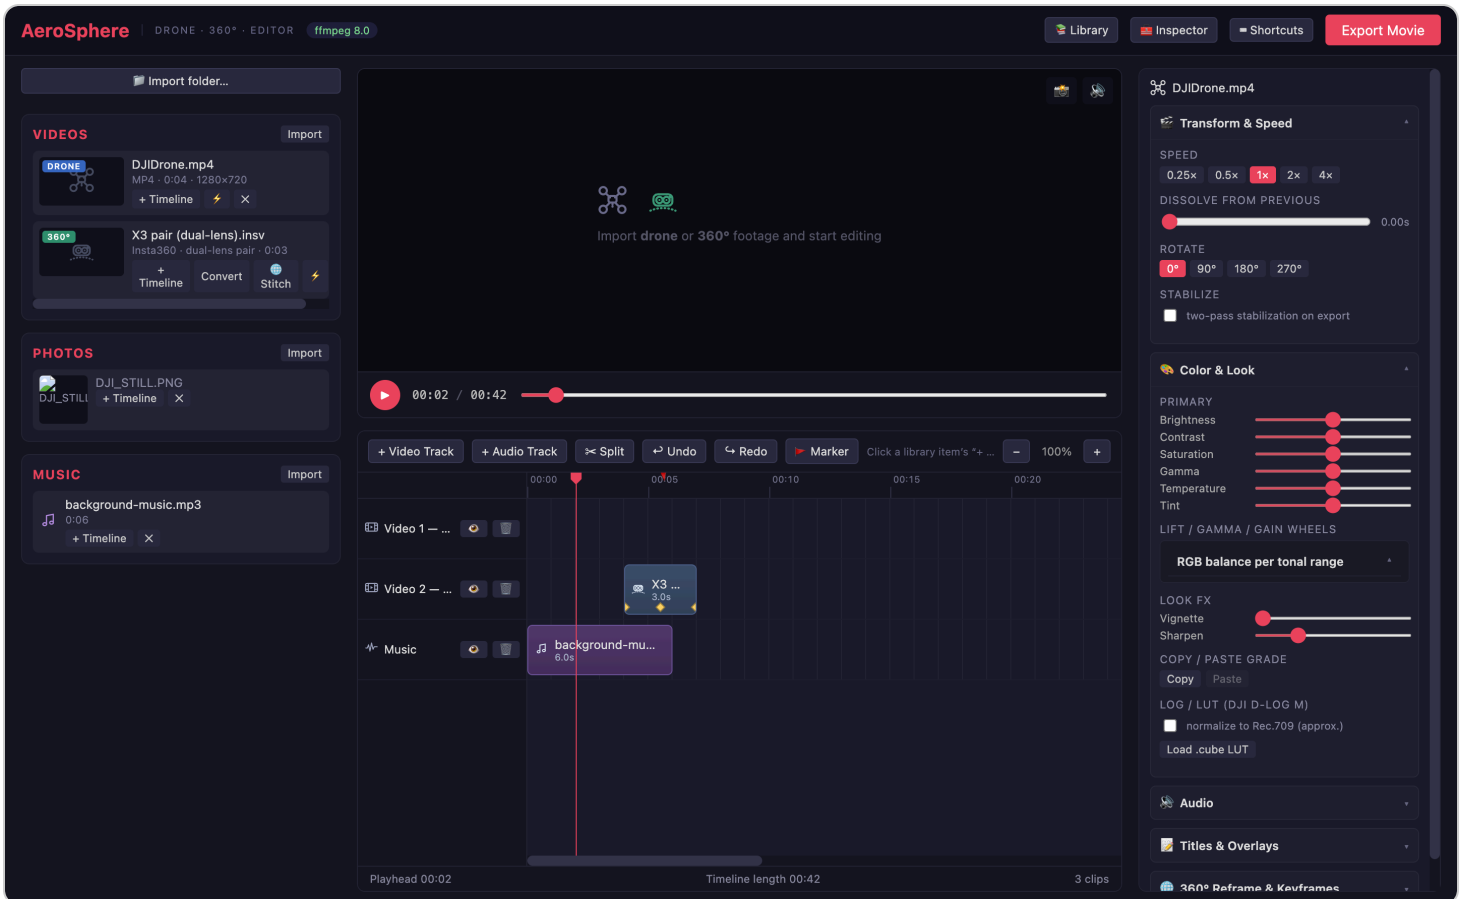

Bring in drone clips (.mp4/.mov), Insta360 files (.insv pairs auto-merge), photos (.png/.jpg/.heic) and music (.mp3/.wav/.m4a).

How: Use **Import** in any library section, click  **Import folder...** to scan a whole folder recursively, or simply **drag & drop** files/folders anywhere onto the window. Importing either lens file of an X3 pair automatically imports both as one 360° item; if the partner file is missing you get a single-lens clip instead.

3 · Building a timeline

Arrange clips on unlimited video/audio tracks. Everything is non-destructive.

How: Press **+ Timeline** on a library item. Drag clips to reposition (with snapping), drag either edge to trim, use **<|> Split** (or **S**) at the playhead, **⌘D** to duplicate, **Delete** to remove and **⇧Delete** for ripple delete (closes the gap).

Markers on the ruler (▶), playhead parked inside the first clip — Split is armed.

4 · Markers & navigation

Mark moments you want to return to — beats, actions, camera changes.

How: Move the playhead and press **M** or click **▶ Marker**. Click a flag to jump there; right-click it to delete. **⬅️/➡️** hop between markers.

5 · Preview & grab stills

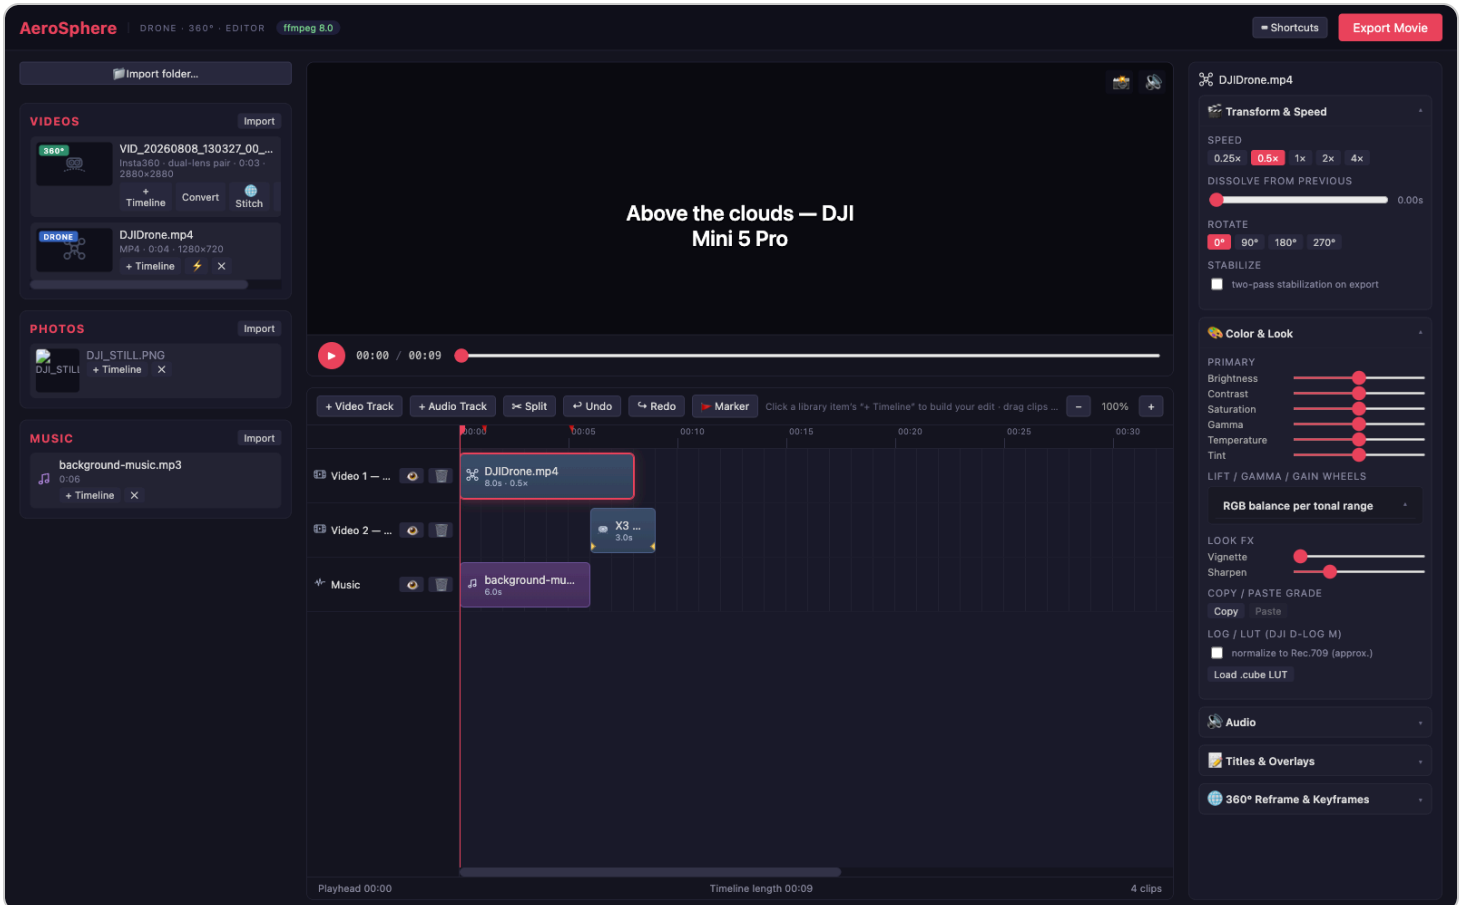

The preview plays your edit with frame-accurate sync; exports the current frame as a PNG still.

How: toggles playback, drag the slider or click the ruler to seek,  mutes all audio. Click  to save the current frame.

6 · Transform, speed & rotation

Rettime any clip from 0.25x to 4x with pitch-corrected audio, rotate in quarter-turns, add fade-ins/outs and stabilize shaky drone passes.

How: Select a clip → Inspector panel  **Transform & Speed**: choose a speed chip, rotation buttons (0°/90°/180°/270°), enable two-pass **Stabilize**, and set fade lengths.

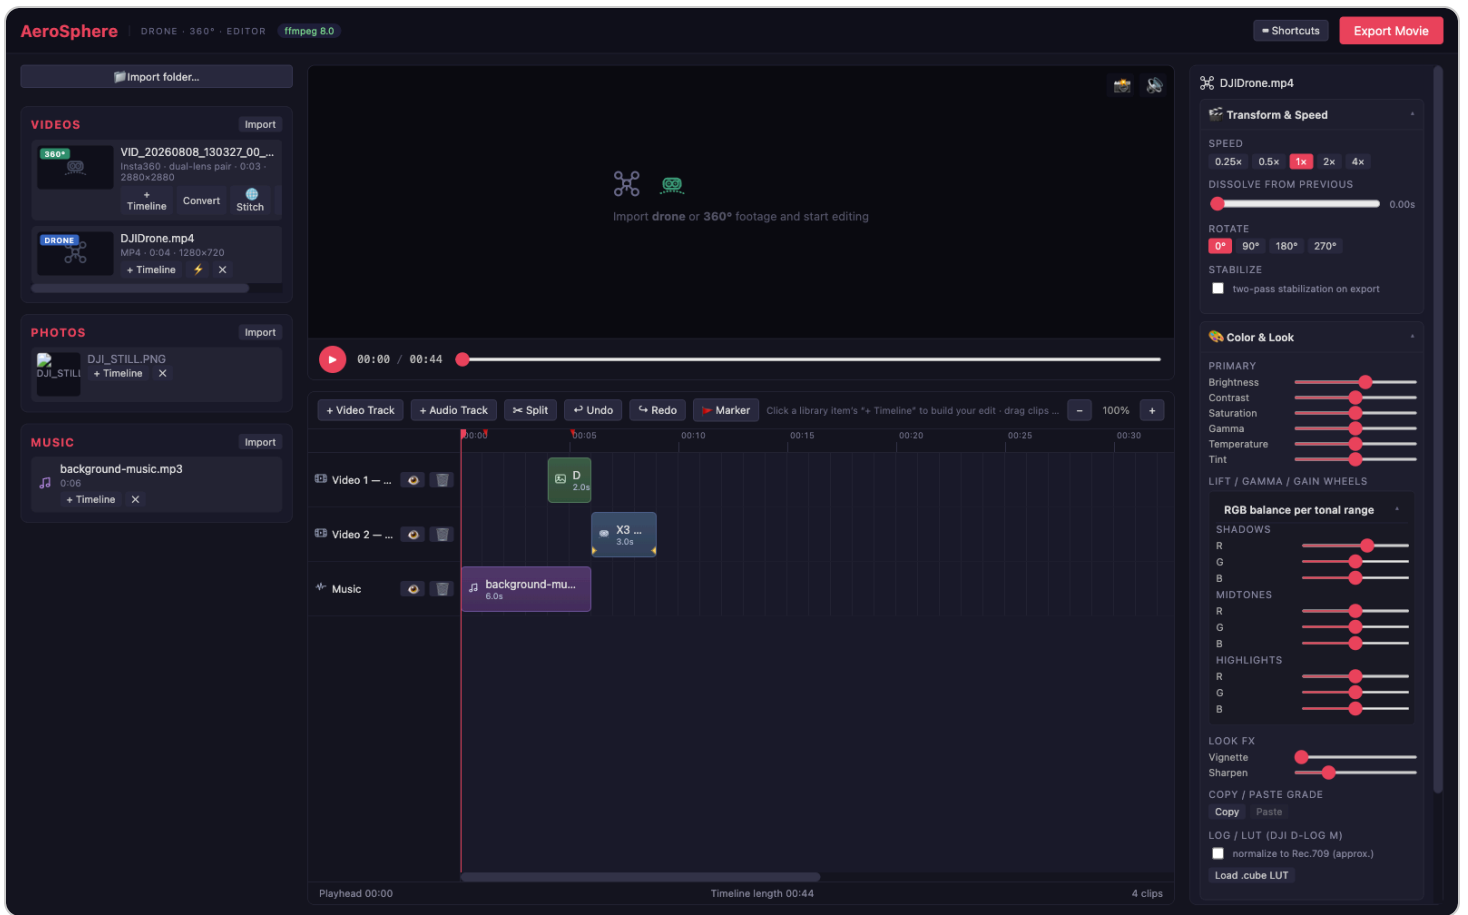

Transform & Speed panel — 0.5x selected, stabilize below.

7 · Color grading

Primary controls plus Resolve-style **Lift/Gamma/Gain RGB wheels**, vignette, sharpen, temperature/tint — and one-click D-Log M normalization with .cube LUT support for DJI footage.

How: Open  **Color & Look**. Drag the primary sliders, expand *RGB balance per tonal range* for the wheels, adjust *Vignette/Sharpen*. Tick *normalize to Rec.709* for D-Log M material and optionally load a DJI official LUT via **Load .cube**. Use **Copy/Paste grade** to match shots instantly.

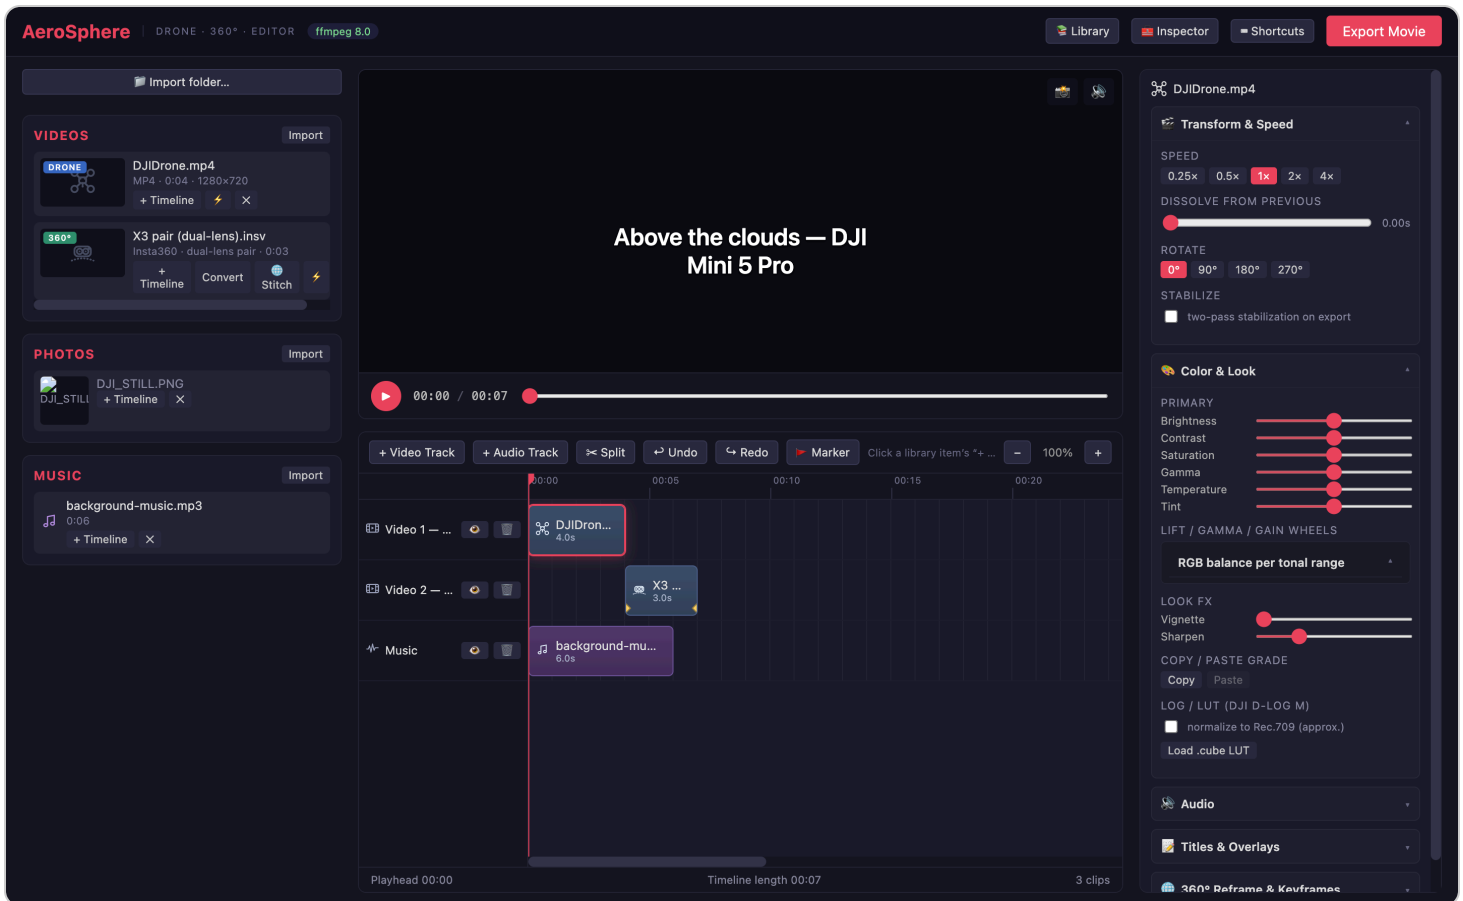

Color & Look panel with the RGB wheels expanded (Shadows Red raised).

8 · Audio (Fairlight-inspired)

Voice-isolation noise reduction, –16 LUFS loudness normalization, bass/treble EQ, 50/60 Hz de-hummer, per-clip volume, fades and full mute. Music tracks can auto-duck under dialogue via sidechain compression.

How: Select any clip →  **Audio** panel. Tick *Voice isolation*, *Normalize loudness*, drag *Bass/Treble*, pick a *De-hum* frequency, set volume/mute and fades. On music clips tick *Auto-duck under video audio*.

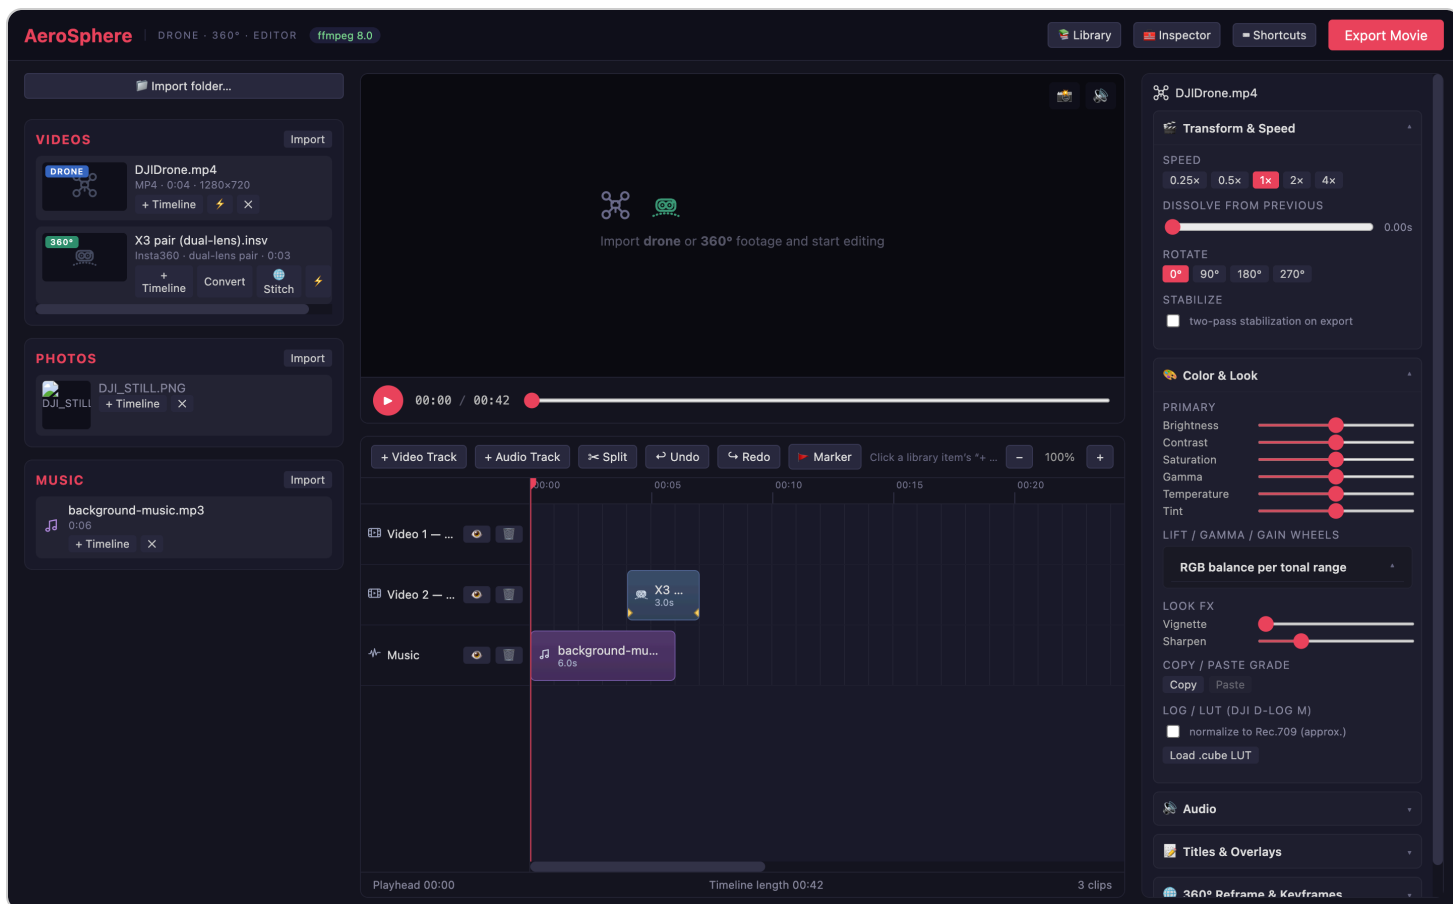

Audio cleanup with voice isolation enabled and bass lifted.

9 · Titles & telemetry overlays

Burn text titles into your movie and overlay the DJI flight-data (.srt) recorded beside your clip.

How:  **Titles & Overlays** → type text, set size and Top/Bottom — it appears live in the preview and is burned into the export. When a sibling .srt exists, tick *burn flight data overlay*.

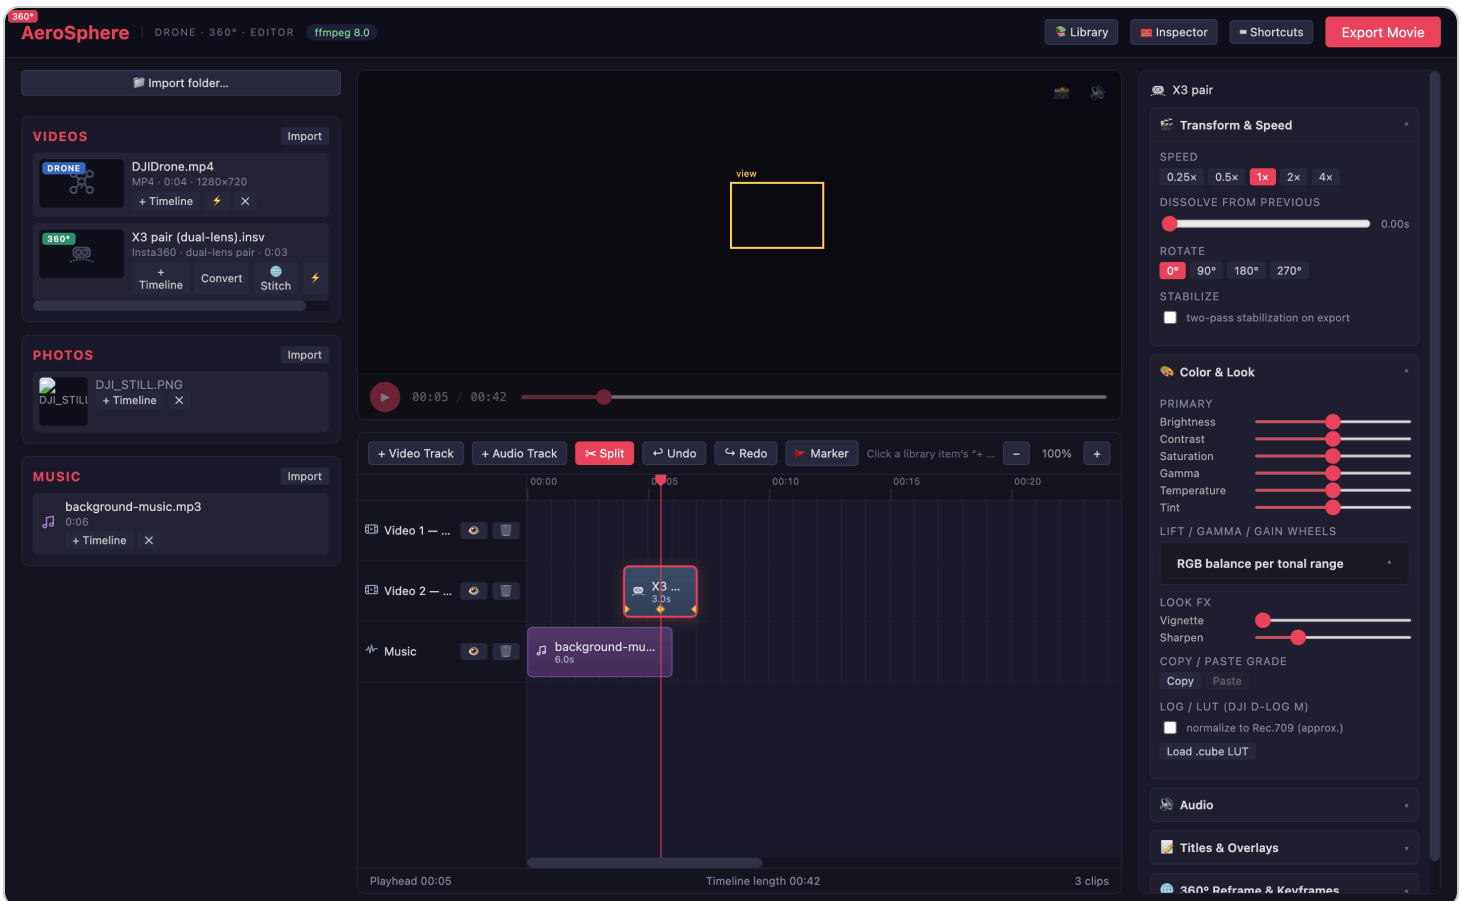

Title editor with the overlay live in the preview.

10 · Insta360 X3 reframing

Turn the full 360° sphere into a flat cinematic shot: keyframe Pan/Tilt/Roll/FOV with eased motion, or apply presets like Tiny Planet and Crystal Ball.

How: Park the playhead inside the 360° clip → 🌐 **360° Reframe & Keyframes** → **+ At playhead**, then edit each keyframe's sliders (or apply a preset). Add more keyframes; motion interpolates automatically. Use **Lens FOV** if the stitch looks too curved. The yellow rectangle in the preview shows the captured area.

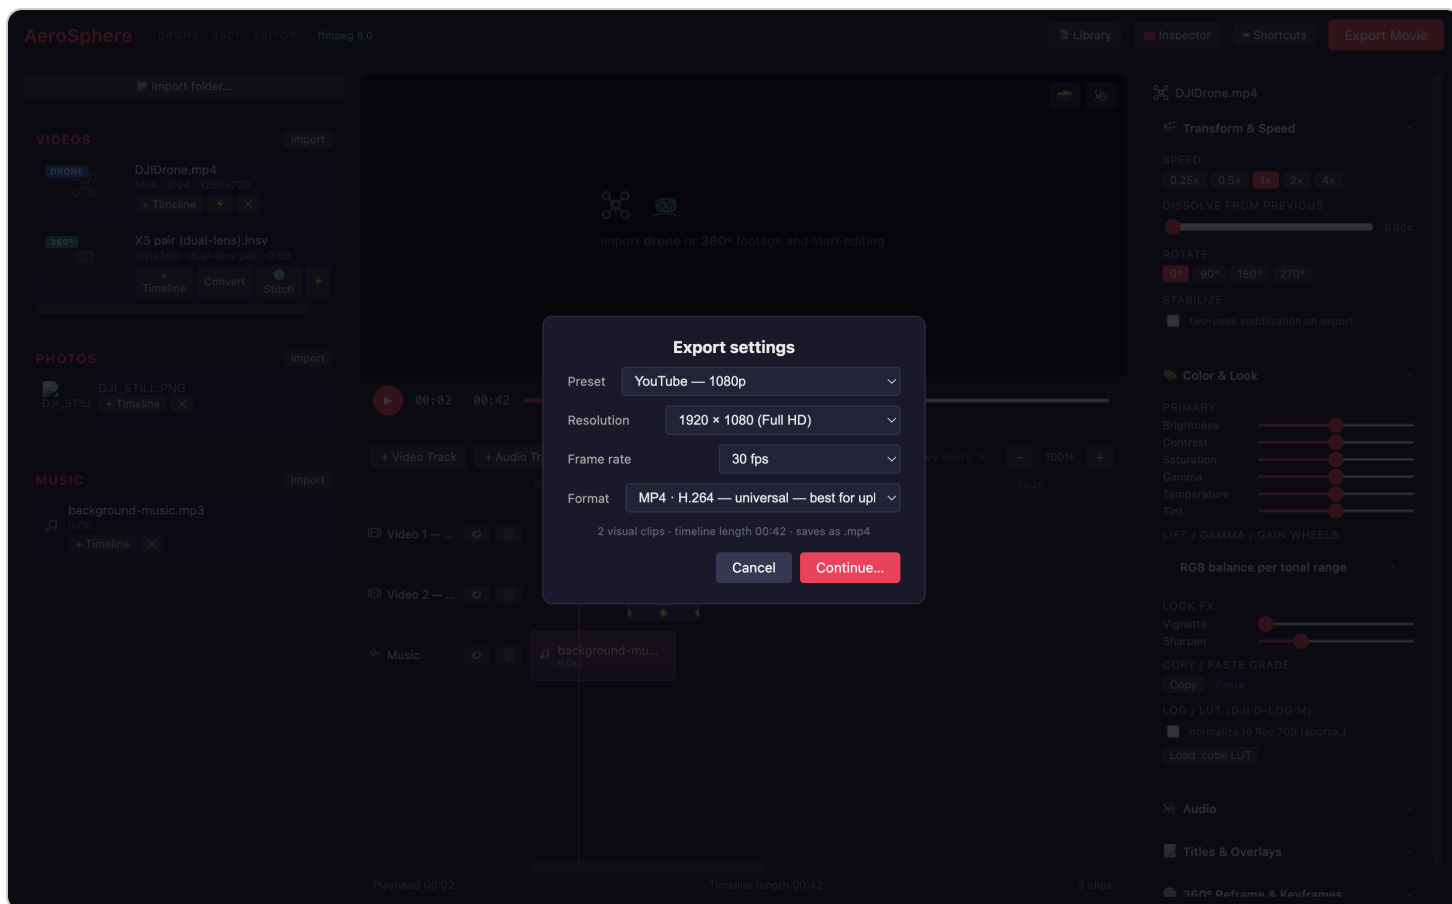

Keyframe added mid-clip with the seven perspective presets available.

11 · Exporting

Deliver masters or social-ready files with exact control over resolution, fps and encoder.

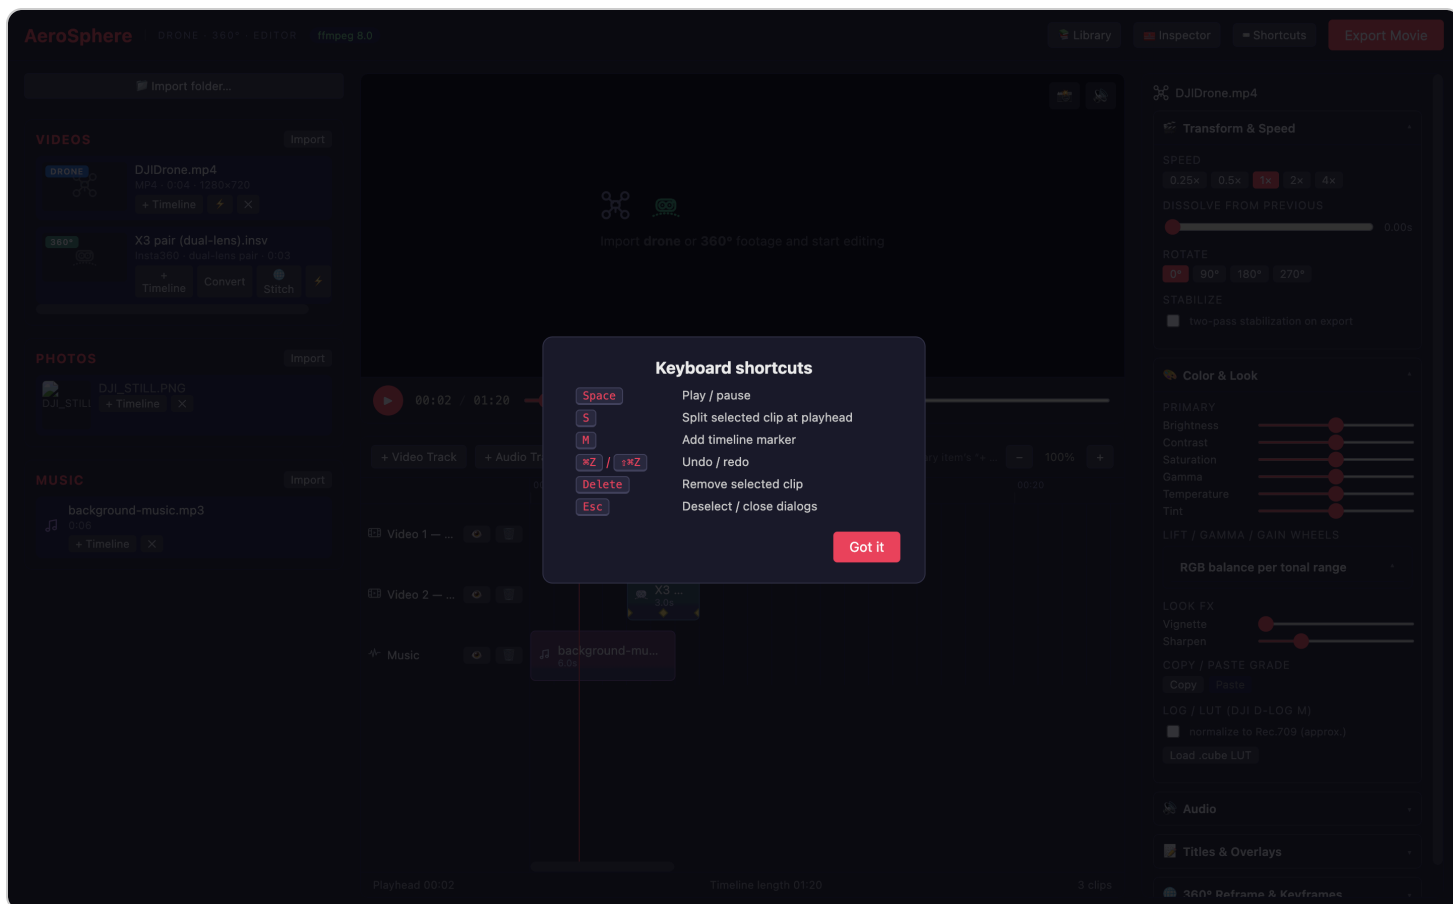

How: Click **Export Movie** → choose a **Preset** (YouTube 1080p/4K/Shorts, Instagram Feed 4:5, Reels, Square, Facebook Feed/Reels, Cinematic ProRes master, H.265 archive) or set Resolution / Frame rate / Format manually (MP4 H.264, MP4 HEVC, WebM VP9, MOV, ProRes 422) → **Continue...** → pick a location → watch live progress (cancel anytime). The save dialog's extension follows the chosen format automatically.

Export settings with platform presets, formats and encoders.

12 · Keyboard shortcuts

Key	Action
Space	Play / pause preview
S	Split selected clip at playhead
M	Add marker at playhead
← / →	Jump between markers
⌘Z / ⇧⌘Z	Undo / redo
⌘D	Duplicate selected clip
Delete / ⇧Delete	Delete / ripple delete clip
?	Show shortcut help
Esc	Deselect / close dialogs

In-app shortcut reference.

13 · Troubleshooting

Symptom	Fix
“ffmpeg missing” badge	Install FFmpeg: <code>brew install ffmpeg</code> , then restart the app
“Project couldn’t be saved (storage full)”	Remove large thumbnails/media from the library; storage is per-browser profile
360° stitch looks warped	Adjust Lens FOV (Inspector → 360°) — 210–230° suits most X3 recordings
Stuttering 5.7K/4K playback	Click ⚡ on the library item to build a 480p proxy (exports always use originals)
HEIC iPhone photos show blank	They are converted to PNG automatically on import (macOS sips)
ProRes files are huge	That is expected for editing masters — deliver with MP4/H.265 instead
